Assertions	2	Strings
Constants	2	String streams
Type safety	2	Vectors
Type casting	2	Enumerations
Limits	3	Classes
Functions	4	Operator overloading
Lambda expressions	5	Inheritance
Namespaces and aliases	5	Polymorphism 28
Random numbers	5	Exceptions
Arrays	6	Templates
Pointers	6	Iterators
C-Strings	8	Containers
Input-output streams	8	Algorithms 40

In the following code snippets, the standard ${\rm I/O}$ library and namespace are always used:

#include <iostream>
using namespace std;

^{*}michele@mathsophy.com

Assertions

⇒ The first argument of a static_assert is a constant expression that must be true:

```
static_assert(8<=sizeof(long),"longs_are_too_small");</pre>
```

Constants

There are two options:

⇒ constexpr must be known at compile time:

```
constexpr int max = 200;
constexpr int c = max + 2;
```

⇒ const variables don't change at runtime. They cannot be declared as constexpr because their value is not known at compile time:

```
// the value of n is not known at compile time
const int m = n + 1;
```

Type safety

 \Rightarrow Universal and uniform initialisation prevents narrowing conversions from happening:

```
// safe conversions
double x {54.21};
int a {2342};

// unsafe conversions (compile error!)
int y {x};
char b {a};
```

Type casting

⇒ Use static_cast for normal casting, i.e. types that can be converted into each other:

```
// int 15 to double 15.0
double num;
num = static_cast<double>(15);
```

⇒ Use static_cast for casting a void pointer to the desired pointer type:

```
// void * pointer can point to anything
double num;
void *p = #

// back to double type
double *pd = static_cast<double*>(p);
```

⇒ Use reinterpret_cast for casting between unrelated pointer types:

```
// reinterprets a long value as a double one
long n = 53;
double *pd = reinterpret_cast<double *>(&n);

// prints out 2.61855e-322
cout << *pd << endl;</pre>
```

 \Rightarrow Use user-defined type conversions:

```
// User defined type
class MyType
public:
   MyType (int y=1) : x\{y\} {}
    operator int() const { return x; }
    explicit operator double() const { return double(x); }
private:
    int x{0};
};
MyType a(5);
MyType b(7);
// a and b are converted to int by operator int()
// c = 12
int c = a + b;
// b is converted to double by operator double()
// but requires explicit static cast
double = static_cast<double>(b);
```

Limits

 \Rightarrow Use numeric_limits<T> for checking against built-in type limits:

```
#include <limits>

// int type
cout << numeric_limits<int>::min() << endl; // -2147483648
cout << numeric_limits<int>::max() << endl; // 2147483647

// double type
cout << numeric_limits<double>::min() << endl; // 2.22507e-308
cout << numeric_limits<double>::max() << endl; // 1.79769e+308
cout << numeric_limits<double>::lowest() << endl; // -1.79769e+308
cout << numeric_limits<double>::lowest() << endl; // -1.79769e+308
cout << numeric_limits<double>::epsilon() << endl; // 2.22045e-16
cout << numeric_limits<double>::round_error() << endl; // 0.5</pre>
```

Functions

⇒ With default trailing arguments only in the function declaration:

```
// if year is omitted, then year = 2000
void set_birthday(int day, int month, int year=2000);
```

⇒ Omitting the name of an argument if not used anymore in the function definition:

```
// argument year is not used anymore in the function definition
// (doesn't break legacy code!)
void set_birthday(int day, int month, int) { ...}
```

 \Rightarrow With read-only, read-write and copy-by-value parameters:

```
// day input parameter passed by const reference (read-only)
// month output parameter to be changed by the function (read-write)
// year input parameter copied-by-value
void set_birthday(const int& day, int& month, int year);
```

 \Rightarrow Use a function for initialising an object with a complicated initialiser (we might not know exactly when the object gets initialised):

```
const Object& default_value()
{
   static const Object default(1,2,3);
   return default;
}
```

- \Rightarrow Rule of thumb for passing arguments to functions:
 - Pass-by-value for small objects
 - Pointer parameter type if nullptr means no object given
 - Pass-by-const-reference for large objects that are not changed
 - Pass-by-reference for large objects that are changed (output parameters)
 - Return error conditions of the function as return values
- \Rightarrow Function pointer type definition:

```
// pointer to a function returning a void and
// having parameters a pointer to a Fl_Widget and a pointer to a void
typedef void ( *Callback_type )( Fl_Widget*, void* );

// cb is a callback defined as above
Callback_type cb;
```

Lambda expressions

An unnamed function that can be used where a function is needed as an argument or object. It is introduced by [] which are called *lambda introducers*.

 \Rightarrow Without access to local variables:

 \Rightarrow With access to local variables:

Namespaces and aliases

⇒ using declarations for avoiding fully qualified names:

```
// use string instead of std::string
using std::string;

// use cin, cout instead of std::cin, std::cout
using std::cin;
using std::cout;
```

 \Rightarrow using namespace directives for including the whole namespace:

```
using namespace std;
```

 \Rightarrow An alias is a symbolic name that means exactly the same as what it refers to:

```
using value_type = int; // value_type means int
using pchar = char*; // pchar means char*
```

Random numbers

 \Rightarrow C-style:

```
#include <cstdlib>
#include <ctime>

// seed the generator
srand( time(0) );

// integer random number between 0 and RAND_MAX
int n = rand();
```

 \Rightarrow C++ style:

Arrays

 \Rightarrow Range-based for statement:

```
// changes the values and outputs 3579
int arr[] = {2, 4, 6, 8};

for (int& x : arr)
    x++;

// auto lets the compiler use the type of the
// elements in the container because it knows the type
// already
for (auto x : arr)
    cout << x;</pre>
```

6

Pointers

 $\Rightarrow \mbox{ Simple object:}$

```
// simple pointer to double
double *d = new double{5.123};

// read
double dd = *d;

// write
*d = -11.234;

// delete the storage on the free store
delete d;

// reassign: now d points to dd
d = ⅆ
```

 \Rightarrow Dynamic array:

```
// dynamic array of 10 doubles
double *dd = new double[10] {0,1,2,3,4,5,6,7,8,9};

// delete the storage on the free store
delete [] dd;
```

 \Rightarrow Dynamic matrix:

```
// dynamic matrix of 5 x 5 doubles memory allocation
double **m = new double*[5];
for (int i=0; i<5; i++)
    m[i] = new double[5];

// memory initialisation
for (int i=0; i<5; i++)
    for (int j=0; j<5; j++)
        m[i][j] = i*j;

// memory deallocation
for (int i=0; i<5; i++)
    delete[] m[i];
delete[] m;</pre>
```

 \Rightarrow unique_ptr: Holds ownership of a dynamic object according to RAII, i.e. resource acquisition is initialisation. It will automatically destroy the object if needed.

```
#include <memory>

MyVector<int>* my_function()
{
    unique_ptr<MyVector<int>*> p { new MyVector<int>};
    /* ... */
    /* if something goes wrong, deletes the object */
    /* ... */
    return p.release(); // returns the pointer
}
```

C-Strings

 \Rightarrow Legacy strings from C:

```
#include <cstring>
#include <cstdlib>

// C-string for max 10 characters
// long string + null char '\0'
const int SIZE = 10 + 1;
char msg[SIZE] = "Hello!";
```

 \Rightarrow Checking for end of string when looping:

```
// correct looping over C-strings
int i = 0;
while ( msg[i] != '\0' && i < SIZE)
{
   // process msg[i]
}</pre>
```

 \Rightarrow Safe C-string operations:

```
// safe string copy, at most 10 characters are copied
strncpy(msg, srcStr, 10);

// safe string compare, at most 10 characters are compared
strncmp(msg, srcStr, 10);

// safe string concatenation, at most 10 characters are concatenated
strncat(msg, srcStr, 10);
```

 \Rightarrow Conversions:

```
// from C-string to int, long, float
int    n = atoi("567");
long    n = atol("1234567");
double n = atof("12.345");
```

Input-output streams

⇒ Input stream cin, output stream cout, error stream cerr:

```
int number;
char ch;

// read a number followed by a character
// from standard input (keyboard)
// (ignores whitespaces, newlines, etc.)
cin >> number >> ch;
```

```
// write on standard output (display)
cout << number << "_" << ch << endl;

// write error message on standard error (display)
cerr << "Wrong_input!\n";</pre>
```

\Rightarrow Integer format manipulators

Once a manipulator is set, it stays until another one is set, i.e. manipulators are sticky.

```
#include <iomanip>
// set decimal, octal, or hexadecimal notation,
// and show the base, i.e. 0 for octal and 0x for hexadecimal
cout << showbase;</pre>
cout << dec << 1974 << endl;
cout << oct << 1974 << endl;
cout << hex << 1974 << endl;
cout << noshowbase;</pre>
// values can be read from input in decimal, octal
// or hexadecimal format previous unsetting
// of all the flags
cin.unsetf(ios::dec);
cin.unsetf(ios::oct);
cin.unsetf(ios::hex);
// now val can be inserted in any format
cin >> val;
```

⇒ Floating point format manipulators

Once a manipulator is set, it stays until another one is set, i.e. manipulators are sticky.

```
#include <iomanip>

// set default, fixed, or scientific notation
cout << defaultfloat << 1023.984;
cout << fixed << 1023.984;
cout << scientific << 1023.984;

// set precision
cout << setprecision(2) << 1023.984;

// set character text width
cout << setw(10);

// set left or right alignment
cout << left << 1023.984;
cout << right << 1023.984;</pre>
// always show decimal point and zeros
```

```
cout << showpoint << 0.532;

// always show plus sign
cout << showpos << 3.64;</pre>
```

 \Rightarrow Single characters read and write:

```
// read any character from cin (doesn't skip spaces, newlines, etc.)
char nextChar;
cin.get(nextChar);
// loop for keeping reading
// stops when end of line control character (control-d)
// is inserted
while ( cin.get(nextChar) )
    // process character
// write a character to cout
cout.put(nextChar)
// read a whole line of 80 chars
char line[80+1];
cin.getline(line,81);
// put back nextChar to cin, nextChar will be the next
// char read by cin.get()
cin.putback(nextChar);
// put back the last char got from cin.get() to cin
cin.unget();
```

 \Rightarrow If the input pattern is unexpected, it is possible to set the state of cin to failed:

```
try
{
    // check for unexpected input
    char ch;
    if ( cin >> ch && ch != expected_char )
    {
        // put back last character read
        cin.unget();

        // set failed bit
        cin.clear(ios_base::failbit);

        // throw an exception or deal with failed stream
        throw runtime_error("Unexpected_input");
    }
}
catch (runtime_error e)
{
```

```
cerr << "Error!_" << e.what() << "\n";

// check for failure
if (cin.fail())
{
    // clear failed bit
    cin.clear();

    // read wrong input
    string wrong_input;
    cin >> wrong_input;

    cerr << "Got_'" << wrong_input[0] << "'\n";
}

// End of file (eof) or corrupted state (bad)
else return 1;
}</pre>
```

Files

⇒ Accessed by means of ifstream (input) or ofstream (output) objects:

```
#include <fstream>

// open input file
ifstream in_stream {"infile.dat"};

// open output file
ofstream out_stream {"outfile.dat"};
```

⇒ Accessed both in input and output mode by means of fstream objects (not recommended):

```
#include <fstream>

// open file in both input and output mode
fstream fs{"inoutfile.dat", ios_base::in | ios_base::out};
```

 \Rightarrow Opened explicitly (not recommended):

```
#include <fstream>

// input file
ifstream in_stream;

// output file
ofstream out_stream;

// open files
in_stream.open("infile.dat");
out_stream.open("outfile.dat");
```

 \Rightarrow When checking for failure, the status flag needs to be cleared in order to continue working with the file:

```
// check for failure on input file
if ( !in_stream )
    if ( in_stream.bad() ) error("stream_corrupted!");
    if ( in_stream.eof() )
    {
        // no more data available
    if ( in_stream.fail() )
        // some format data error, e.g. expected
        // an integer but a string was read
        // recovery is still possible
        // set back the state to good
        // before attempting to read again
        in_stream.clear();
        // read again
        string wrong_input;
        in_stream >> wrong_input;
    }
```

⇒ As for the standard input, if the input pattern is unexpected, it is possible to set the state of the file to failed and try to recover somewhere else, e.g. by throwing an exception:

```
try
    // check for unexpected input
    char ch;
    if ( in_stream >> ch && ch != expected_char )
        // put back last character read
        in_stream.unget();
        // set failed bit
        in_stream.clear(ios_base::failbit);
        // throw an exception or deal with failed stream
        throw runtime_error("Unexpected_input");
catch (runtime_error e)
    cerr << "Error!" << e.what() << "\n";
    // check for failure
   if (in_stream.fail())
    {
        // clear failed bit
```

```
in_stream.clear();

// read wrong input
string wrong_input;
in_stream >> wrong_input;

cerr << "Got_'" << wrong_input[0] << "'\n";
}
// end-of-file or bad state
else return 1;
}</pre>
```

 \Rightarrow Read and write:

```
// read/write data
in_stream >> data1 >> data2;
out_stream << data1 << data2;</pre>
```

 \Rightarrow Read a line:

```
string line;
getline(in_stream, line);
```

 \Rightarrow Ignore input (extract and discard):

```
// ignore up to a newline or 9999 characters
in_stream.ignore(9999,'\n');
```

 \Rightarrow Move the file pointer:

```
// skip 5 characters when reading (seek get)
in_stream.seekg(5);
// skip 8 characters when writing (seek put)
out_stream.seekp(8);
```

 \Rightarrow Checking for end of file:

```
// the failing read sets the EOF flag but avoids further processing
while ( in_stream >> next )
{
    // process next
}

// check the EOF flag
if ( in_stream.eof() )
    cout << "EOF_reached!" << endl;</pre>
```

⇒ When a file object gets out of scope, the file is closed automatically, but explicit close is also possible (not recommended):

```
// explicitily close files
in_stream.close();
out_stream.close()
```

GNU GPL v3.0

Strings

 \Rightarrow Strings as supported by the C++ standard library:

```
#include <string>

// initialisation
string s1 = "Hello";
string s2("World");
string s3{"World"};
```

 \Rightarrow Fill constructor:

```
string s4{string(5,'*')}; // fill constructor "*****"
```

 \Rightarrow Substring constructor from a certain position and a given optional length:

```
string s5{string(string{"Hello,_world!"},0,5)}; // "Hello"
string s6{string(string{"Hello,_world!"},7)}; // "world!"
```

 \Rightarrow Buffer constructor from a character array:

```
string s7{string("Hello, world!",5)}; // "Hello"
```

 \Rightarrow Concatenation:

```
// concatenation
string s3 = s1 + ", " + s2;
```

⇒ Read a line:

```
// read a line
string line;
getline(cin,line);
```

 \Rightarrow Access to a character:

```
// access to the ith character (no illegal index checking)
s1[i];

// access to the ith character (with illegal index checking)
s1.at(i);
```

 \Rightarrow Append:

```
// append
s1.append(s2);
```

 \Rightarrow Size and length:

```
// size and length
sl.size();
sl.length();
```

 \Rightarrow Substring:

```
// substring from position 5 and length 4 characters
string substring;
substring = s4.substr(5,4);
```

 \Rightarrow Find:

```
// find (returns string::npos if not found)
size_t pos;
pos = s3.find("World");
if (pos == string::npos)
    cerr << "Error:_String_not_found!\n";

// find starting from position 5
s3.find("1",5);</pre>
```

 \Rightarrow C-string:

```
// C-string
s3.c_str();
```

 \Rightarrow Conversions:

```
// from string to int, long, float
int    n = stoi("456");
long    n = stol("1234567");
double n = stod("12.345");

// from numeric type to string
string s = to_string(123.456);
```

String streams

A string is used as a source for an input stream or as a target for an output stream.

⇒ Input string stream: istringstream

```
#include <sstream>

// input string stream
istringstream data_stream{"1.234_-5643.32"};

// read numbers from data stream
double val;
while ( is >> val )
    cout << val << endl;</pre>
```

 \Rightarrow Output string stream: ostringstream

```
#include <sstream>

// output string stream
ostringstream data_stream;

// the same manipulators of input-output streams
// can be used
data_stream << fixed << setprecision(2) << showpos;
data_stream << 6.432 << "_" << -313.2134 << "\n";

// the str() method returns the string in the stream
cout << data_stream.str();</pre>
```

Vectors

 \Rightarrow Vectors as supported by the C++ standard library:

```
#include <vector>

// vector with base type int
vector<int> v = {2, 4, 6, 8};

// vector with 10 elements all initialised to 0
vector<int> v(10);
```

 \Rightarrow Access:

```
// unchecked access to the ith element
cout << v[i];
// checked access to the ith element
cout << v.at(i);</pre>
```

 \Rightarrow Add:

```
// add an element
v.push_back(10);
```

 \Rightarrow Resize:

```
// resize to 20 elements
// new elements are initialised to 0
v.resize(20);
```

 \Rightarrow Loop over:

```
// range-for-loop
for (auto x : v)
   cout << x << endl;

// auto gives to x the same type of the element on the right
// hand side of the assignment, in this case a vector::iterator
for (auto x = v.begin(); x<v.end(); x++)
   cout << *x << endl;</pre>
```

 \Rightarrow Size and capacity:

```
// size
cout << v.size();

// capacity: number of elements currently allocated
cout << v.capacity();</pre>
```

 \Rightarrow Reserve more capacity:

```
// reserve (reallocate) more capacity e.g. at least 64 ints
v.reserve(64);
```

⇒ Throws an out_of_range exception if accessed out of bounds:

```
// out of bounds access
vector<int> v = {2, 4, 6, 8};

try
{
    cout << v.at(7);
} catch (out_of_range e)
{
    // access error!
}</pre>
```

Enumerations

 \Rightarrow enum class defines symbolic constants in the scope of the class:

```
// enum definition
enum class Weekdays
{
    mon=1, tue, wed, thu, fri
};

// usage
Weekdays day = Weekdays::tue;
```

⇒ ints cannot be assigned to enum class and vice versa:

```
// errors!
Weekdays day = 3;
int d = Weekdays::wed;
```

 \Rightarrow A conversion function should be written which uses unchecked conversions:

```
// valid
Weekdays day = Weekdays(2);
int d = int(Weekdays::fri);
```

Classes

 \Rightarrow Class using dynamic arrays:

```
#include <algorithm>
class MyVector
public:
    // constructor
    explicit MyVector();
    // explicit constructor (avoids type conversions)
    explicit MyVector(size_t);
    // constructor with initialiser list
    explicit MyVector(initializer_list<double>);
    // copy constructor (pass by
    // reference, no copying!)
    MyVector(const MyVector&);
    // move constructor
    MyVector (MyVector&&);
    // copy assignment
    MyVector& operator=(const MyVector&);
    // move assignment
   MyVector& operator=(MyVector&&);
    // virtual destructor
    virtual ~MyVector() { if (e) delete[] e; }
    // subscript operators
    // write
    double& operator[](size_t i) { return e[i]; }
    // read
    const double& operator[](size_t i) const { return e[i]; };
    // size
    size_t size() const { return n; }
    // capacity
    size_t capacity() const { return m; }
    // reserve
    void reserve(size_t);
    // resize
    void resize(size_t);
    // push back
    void push_back(double);
```

```
private:
    size_t n{0}; // size
    size_t m{0}; // capacity
    double *e{nullptr};
};
```

\Rightarrow Constructors definitions

By using the explicit qualifier, undesired type conversions are avoided. If you give no constructor, the compiler will generate a default constructor that does nothing. If you give at least one constructor, then the compiler will generate no other constructors. Notice the use of double () as the default value (0.0) when initialising the vector.

```
// constructor with member initialisation list
MyVector::MyVector(size_t s) : n{s}, m{s}, e{new double[n]}
{
    for (int i=0; i<n; i++) e[i] = double();
}

// constructor with initialiser list parameter
MyVector::MyVector(initializer_list<double> 1)
{
    n = m = 1.size();
    e = new double[n];
    copy(l.begin(),l.end(),e);
}
```

\Rightarrow Copy constructor

The argument is passed by const reference, i.e. no copies and no changes. If not defined, C++ automatically adds the default copy constructor. This might not be correct if dynamic variables are used, because class members are simply copied

```
// copy constructor
MyVector::MyVector(const MyVector& v)
{
    n = v.n;
    m = v.m;
    e = new double[n];
    copy(v.e, v.e+v.n, e);
}
```

\Rightarrow Move constructor

```
// move constructor
MyVector::MyVector(MyVector&& v)
{
    n = v.n;
    m = v.m;
    e = v.e;
    v.n = 0;
    v.m = 0;
    v.e = nullptr;
}
```

\Rightarrow Copy assignment

If not defined, C++ automatically adds the default assignment operator. It might not be correct if dynamic variables are used, because class members are simply copied

```
// copy assignment
MyVector& MyVector::operator=(const MyVector& rv)
{
    // check for self assignment
    if (this == &rv)
        return *this;
    // check if new allocation is needed
    if (rv.n > m)
    {
        if (e) delete[] e;
        e = new double[rv.n];
        m = rv.n;
    }
    // copy the values
    copy(rv.e,rv.e+rv.n,e);
    n = rv.n;
    return *this;
}
```

 \Rightarrow Move assignment

```
// move assignment
MyVector& MyVector::operator=(MyVector&& rv)
{
    delete[] e;
    n = rv.n;
    m = rv.m;
    e = rv.e;
    rv.n = 0;
    rv.m = 0;
    rv.e = nullptr;
    return *this;
}
```

 \Rightarrow Reserve (real location), resize and push back

```
// reserve
void MyVector::reserve(size_t new_m)
{
    if (new_m <= m)
        return;
    // new allocation
    double* p = new double[new_m];
    if (e)
    {
        copy(e,e+n,p);
        delete[] e;
}</pre>
```

```
e = p;
    m = new_m;
}

// resize

void MyVector::resize(size_t new_n)
{
    reserve(new_n);
    for (size_t i = n; i < new_n; i++) e[i] = double();
    n = new_n;
}

// push back
void MyVector::push_back(double d)
{
    if (m == 0)
        reserve(8);
    else if (n == m)
        reserve(2*m);
    e[n] = d;
    ++n;
}</pre>
```

\Rightarrow Constructor invocations

```
// constructor with size
MyVector v1(4);

// constructor with initialiser list
MyVector v2{1,2,3,4};

// copy constructor
MyVector v3{v2};
```

\Rightarrow Move invocations

Avoids copying when moving is sufficient, e.g. when returning an object from a function:

```
// example of a function returning an object
MyVector func()
{
    MyVector v4{11,12,13,14,15};
    for (size_t i=0; i<v4.size(); i++) v4[i] += i;
    return v4;
}

// move constructor
MyVector v5 = func();

// move assignment
v4 = func();</pre>
```

Operator overloading

The behaviour is different if an operator is overloaded as a class member or friend function.

 \Rightarrow As class members

```
class Euro
{
  public:
    // constructor for euro
    Euro(int euro);
    // constructor for euro and cents
    Euro(int euro, int cents);
    Euro operator+(const Euro& amount);

private:
    int euro;
    int cents;
};
```

 \Rightarrow The definition above requires a calling object:

```
// works, equivalent to Euro{5}.operator+( Euro{2} )
Euro result = Euro{5} + 2;

// doesn't work, 2 is not a calling object of type Euro !
Euro result = 2 + Euro{5};
```

 \Rightarrow As friend members

 \Rightarrow The definition above works for every combination because int arguments are converted by the constructor to Euro objects:

```
// works, equivalent to Euro{5} + Euro{2}
Euro result = Euro{5} + 2;

// works, equivalent to Euro{2} + Euro{5}
Euro result = 2 + Euro{5};
```

Inheritance

 \Rightarrow Abstract base class (excerpt):

```
class Shape : public Widget
public:
    // no copy constructor allowed
   Shape(const Shape&) = delete;
    // no copy assignment allowed
    Shape& operator=(const Shape&) = delete;
    // virtual destructor
   virtual ~Shape() {}
    // overrides Fl_Widget::draw()
   void draw();
    // moves a shape relative to the current
    // top-left corner (call of redraw()
    // might be needed)
   void move(int dx, int dy);
    // setter and getter methods for
    // color, style, font, transparency
    // (call of redraw() might be needed)
   void set_color(Color_type c);
   void set_color(int c);
    Color_type get_color() const { return to_color_type(new_color); }
    void set_style(Style_type s, int w);
    Style_type get_style() const { return to_style_type(line_style); }
    void set_font(Font_type f, int s);
protected:
    // Shape is an abstract class,
    // no instances of Shape can be created!
    Shape() : Widget() {}
    // protected virtual methods to be overridden
    // by derived classes
   virtual void draw_shape() = 0;
    virtual void move_shape(int dx, int dy) = 0;
    // protected setter methods
    virtual void set_color_shape(Color_type c) {
        new_color = to_fl_color(c);
    virtual void set_color_shape(int c) {
        new_color = to_fl_color(c);
   virtual void set_style_shape(Style_type s, int w);
   virtual void set_font_shape(Font_type f, int s);
    // helper methods for FLTK style and font
```

```
void set_fl_style();
    void restore_fl_style();
    void set_fl_font();
    void restore_fl_font() { fl_font(old_font,old_fontsize); }
    // test method for checking resize calls
    void draw_outline();
private:
    Fl_Color new_color{Fl_Color()}; // color
    Fl_Color old_color{Fl_Color()};  // old color
Fl_Font new_font{0};  // font
                                         // old font
    Fl_Font old_font{0};
                                      // font size
// old font size
    Fl_Fontsize new_fontsize{0};
    Fl_Fontsize old_fontsize(0);
                                         // line style
    int line_style{0};
                                         // line width
    int line_width{0};
};
```

 \Rightarrow A base class can be a derived class itself:

```
// Shape is a base class for Line
// but Shape is derived from Widget
class Line : public Shape
{
    ...
};
```

⇒ Disabling copy constructors and assignment

Notice the = delete syntax for disabling them. If they were allowed, slicing might occur when derived objects are copied into base objects. Usually, sizeof(Shape) <= sizeof(derived classes from Shape). By allowing copying, some attributes are not be copied, which might lead to crashes when member functions of the derived classes are called! Note that slicing is the class object equivalent of integer truncation.

```
class Shape : public Widget
{
  public:
     // no copy constructor allowed
     Shape(const Shape&) = delete;
     // no copy assignment allowed
     Shape& operator=(const Shape&) = delete;
     ...
};
```

⇒ Virtual destructor

Destructors should be declared virtual. When derived objects are referenced by base class pointers, the destructor of the derived class is called if it is declared virtual.

```
class Shape : public Widget
{
public:
```

```
...
// virtual destructor
virtual ~Shape() {}
...
};
```

\Rightarrow Protected constructor

By declaring the constructor as protected, no instances of this class can be created by a user. Since Shape is an abstract class, it should be used only as a base class for derived classes.

```
class Shape : public Widget
{
    ...
protected:
    ...
    // Shape is an abstract class
    // no instances of Shape can be created!
    Shape() : Widget() {}
    ...
};
```

\Rightarrow Protected member functions

By declaring member functions as protected, access is restricted only to the class itself or to derived classes, a user cannot call such functions. This is useful for helper functions which are not supposed to be called directly outside the class.

```
class Shape : public Widget
{
    ...
protected:
    ...
    // helper methods for FLTK style and font
    void set_fl_style();
    void restore_fl_style();
    void set_fl_font();
    void set_fl_font();
    void restore_fl_font() { fl_font(old_font,old_fontsize); }
    ...
};
```

\Rightarrow Pure virtual functions

The protected member functions <code>draw_shape()</code> and <code>move_shape()</code> are pure virtual functions, i.e. a derived class must provide an implementation for them. Notice the syntax which signals that the function is a pure virtual function. When a class has function members that are declared as pure virtual functions, then the class becomes an abstract class.

```
class Shape : Widget
{
    ...
protected:
```

```
// protected virtual methods to be overridden by
// derived classes
virtual void draw_shape() = 0;
virtual void move_shape(int dx, int dy) = 0;
...
};
```

\Rightarrow Virtual functions

The protected member functions set_color_shape() is declared as a virtual function and an implementation is provided. This means that if a derived class does not override the implementation of the base class, the derived class inherits the implementation from the base class.

```
class Shape : Widget
{
    ...
protected:
    ...
    // protected setter methods
    virtual void set_color_shape(Color_type c) {
        new_color = to_fl_color(c);
    }
    virtual void set_color_shape(int c) {
        new_color = to_fl_color(c);
    }
    ...
};
```

⇒ A derived class from the base class Shape:

```
class Line : public Shape
public:
    Line(pair<Point, Point> line) : l{line} {
        resize_shape(l.first,l.second);
    }
    virtual ~Line() {}
    pair<Point, Point> get_line() const { return l; }
    void set_line(pair<Point,Point> line) { l = line; }
protected:
    void draw_shape() {
        fl_line(l.first.x, l.first.y, l.second.x, l.second.y);
    void move_shape(int dx, int dy) {
        l.first.x += dx; l.first.y += dy;
        1.second.x += dx; l.second.y += dy;
        resize_shape(l.first,l.second);
private:
    pair<Point, Point> 1;
```

 \Rightarrow Line is derived from Shape, it models the relationship that a Line is a Shape

```
class Line : public Shape
{
    ...
};
```

⇒ Line has its own getter and setter functions for accessing its own internal private representation:

```
class Line : public Shape
{
  public:
    ...
    pair<Point,Point> get_line() const { return 1; }
    void set_line(pair<Point,Point> line) { l = line; }
    ...
  private:
    pair<Point,Point> l;
};
```

 \Rightarrow Line specialises the virtual functions draw_shape() and move_shape() according to its representation:

```
class Line : public Shape
{
  public:
    ...
  protected:
    void draw_shape() {
        fl_line(l.first.x, l.first.y, l.second.x, l.second.y);
    }
    void move_shape(int dx, int dy) {
        l.first.x += dx; l.first.y += dy;
        l.second.x += dx; l.second.y += dy;
        resize_shape(l.first,l.second);
    }
    ...
};
```

 \Rightarrow Circle is also derived from Shape, a Circle is also a Shape.

```
class Circle : public Shape
{
public:
    Circle(Point a, int rr) : c{a}, r{rr} {
        resize_shape(Point{c.x-r,c.y-r},Point{c.x+r,c.y+r});
    }
    virtual ~Circle() {}
    Point get_center() const { return c; }
    void set_center(Point p) {
        c = p;
```

```
resize_shape(Point{c.x-r,c.y-r},Point{c.x+r,c.y+r});
}
int get_radius() const { return r; }
void set_radius(int rr) {
    r = rr;
    resize_shape(Point{c.x-r,c.y-r},Point{c.x+r,c.y+r});
}
protected:
    void draw_shape() {
        Point tl = get_tl();
        Point br = get_br();
        fl_arc(tl.x,tl.y,br.x-tl.x,br.y-tl.y,0,360);
}
void move_shape(int dx,int dy) {
        c.x += dx; c.y += dy;
        resize_shape(Point{c.x-r,c.y-r},Point{c.x+r,c.y+r});
    }
private:
    Point c{}; // center
    int r{0}; // radius
};
```

Polymorphism

⇒ From a window perspective, it is possible to attach and draw any type of widget, and the window just needs to call the Fl_Widget::draw() method:

```
void Window::draw(Fl_Widget& w) {
    w.draw();
}
```

⇒ Since Fl_Widget::draw() is a pure virtual function, it is overridden by Shape::draw(), which in turn calls the pure virtual function Shape::draw_shape(), which gets specialised in every derived class, e.g. as in Line or Circle:

```
void Shape::draw() {
    set_fl_style();
    if ( is_visible() ) draw_shape();
    restore_fl_style();
}

void Circle:: draw_shape() {
    Point tl = get_tl();
    Point br = get_br();
    fl_arc(tl.x,tl.y,br.x-tl.x,br.y-tl.y,0,360);
}

void Line::draw_shape() {
    fl_line(l.first.x, l.first.y, l.second.x, l.second.y);
}
```

⇒ Polymorphism is allowed by the virtual keyword which guarantees late binding: the call w.draw() inside Windows::draw() binds to the draw_shape() function of the actual object referenced, either to a Line or Circle instance.

```
Window win;
Line diagonal { {Point{200,200},Point{250,250}} };
Circle c1{Point{100,200},50};

win.draw(diagonal); // calls Line::draw_shape()
win.draw(c1); // calls Circle::draw_shape()
```

Exceptions

 \Rightarrow The value thrown by throw can be of any type.

```
// exception class
class My_exception
public:
   My_exception(string s);
    virtual ~My_exception();
    friend ostream& operator<<(ostream& os, const My_exception& e);</pre>
protected:
   string msg;
};
try
    throw My_exception("error");
catch (My_exception& e)
    // error stream
    cerr << e;
// everything else
catch (...)
    exit(1);
```

 \Rightarrow The standard library defines a hierarchy of exceptions. For example runtime_error can be thrown when runtime errors occur:

```
try
{
    throw runtime_error("unexpected_result!");
}
catch (runtime_error& e)
{
    // error stream
```

29

```
cerr << "runtime_error:_" << e.what() << "\n";
    return 1;
}</pre>
```

⇒ Functions throwing exceptions should list the exceptions thrown in the exception specification list.

These exceptions are not caught by the function itself!

```
// exceptions of type DivideByZero or OtherException are
// to be caught outside the function. All other exceptions
// end the program if not caught inside the function.
void my_function() throw (DivideByZero, OtherException);

// empty exception list, i.e. all exceptions end the
// program if thrown but not caught inside the function.
void my_function() throw ();

// all exceptions of all types treated normally.
void my_function();
```

 \Rightarrow Basic guarantee: Any part of your code should either succeed or throw an exception without leaking any resource.

```
// Does local cleanup avoiding leaking of resources
// if exception occurs
void my_function(void)
{
    void *p;
    socket *s;

    try
    {
        /* code that acquires some resource (memory, socket, etc.) */
        /* and might throw an exception */
    }
    catch (...)
    {
        /* local cleanup here */
        delete p; /* free memory */
        s.release(); /* release socket */
        /* re-throw because function didn't succeed */
        throw()
    }
}
```

Templates

Types are used as parameters for a function or a class. C++ does not need the template declaration. Always put the template definition in the header file directly!

 \Rightarrow Function template:

```
// generic swap function
template<class T>
void swap(T& a, T& b)
{
    T temp = a;
    a = b;
    b = temp;
}
int a, b;
char c, d;

// swaps two ints
swap(a, b);

// swaps two chars
swap(c, d);
```

 \Rightarrow Class templates: extending MyVector with templates. Class templates are also called $type\ generators$.

```
template<class T>
class MyVector
public:
   // constructor
    explicit MyVector();
    // constructor with size
    explicit MyVector(size_t);
    // constructor with initialiser list
    explicit MyVector(initializer_list<T>);
    // copy constructor (pass by
    // reference, no copying!)
    MyVector(const MyVector&);
    // move constructor
   MyVector (MyVector&&);
    // copy assignment
   MyVector& operator=(const MyVector&);
    // move assignment
   MyVector& operator=(MyVector&&);
    // virtual destructor
    virtual ~MyVector() { if (e) delete[] e; }
    // subscript operators
    // write
    T& operator[](size_t i) { return e[i]; }
    // read
    const T& operator[](size_t i) const { return e[i]; };
    // size
    size_t size() const { return n; }
    // capacity
    size_t capacity() const { return m; }
    // reserve
```

```
void reserve(size_t);
// resize
void resize(size_t);
// push back
void push_back(T);
private:
    size_t n{0}; // size
    size_t m{0}; // capacity
    T *e{nullptr};
};
```

 \Rightarrow Method definition with templates:

```
// copy assignment
template<class T>
MyVector<T>& MyVector<T>::operator=(const MyVector<T>& rv)

{
    // check for self assignment
    if (this == &rv)
        return *this;
    // check if new allocation is needed
    if (rv.n > m)
    {
        if (e) delete[] e;
        e = new T[rv.n];
        m = rv.n;
    }
    // copy the values
    copy(rv.e,rv.e+rv.n,e);
    n = rv.n;
    return *this;
}
```

 \Rightarrow Specialisation or template instantiation:

```
// MyVector of double
MyVector<double> v4{11,12,13,14,15};

// function returning a MyVector of double
MyVector<double> func()
{
    MyVector<double> v4{11,12,13,14,15};
    for (size_t i=0; i<v4.size(); i++) v4[i] += i;
    return v4;
}</pre>
```

 \Rightarrow Integer template parameters

```
// Wrapper class for an array
template<class T, size_t N>
class Wrapper
{
```

```
public:
    Wrapper() { for(T& e : v) e=T(); }
    ~Wrapper() {}
    T& operator[](int n) { return v[n]; };
    const T& operator[](int n) const { return v[n]; };
    size_t size() const { return N; }

private:
    T v[N];
};

// usage
Wrapper<double,5> array;
Wrapper<char,3> array;
```

\Rightarrow Class template parameter

```
// Usage of an allocator as a class template parameter
// Generalises MyVector for data types without a default constructor
// and with customised memory management
template<class T, class A=allocator<T>>
class MyVector
public:
    // constructor
    explicit MyVector();
    // constructor with size and default value
    explicit MyVector(size_t,T def = T());
   // constructor with initialiser list
    explicit MyVector(initializer_list<T>);
    // copy constructor (pass by
    // reference, no copying!)
   MyVector(const MyVector&);
    // move constructor
   MyVector (MyVector&&);
    // copy assignment
   MyVector& operator=(const MyVector&);
    // move assignment
   MyVector& operator=(MyVector&&);
   // virtual destructor
   virtual ~MyVector();
   // subscript operators
    // write
   T& operator[](size_t i) { return e[i]; }
    // read
    const T& operator[](size_t i) const { return e[i]; };
    // size
   size_t size() const { return n; }
    // capacity
    size_t capacity() const { return m; }
    // reserve
   void reserve(size_t);
    // resize
    void resize(size_t,T def = T());
```

GNU GPL v3.0

```
// push back
    void push_back(T);
private:
   A alloc;
   size_t n{0}; // size
   size_t m{0}; // capacity
    T *e{nullptr};
};
// reserve
template<class T,class A>
void MyVector<T, A>::reserve(size_t new_m)
    if (new_m <= m)
        return;
    // new allocation
    T* p = alloc.allocate(new_m);
    if (e)
    {
        // copy
        for (size_t i=0; i<n; ++i) alloc.construct(&p[i],e[i]);</pre>
        // destroy
        for (size_t i=0; i<n; ++i) alloc.destroy(&e[i]);</pre>
        // deallocate
        alloc.deallocate(e,m);
    }
   e = p;
   m = new_m;
```

 \Rightarrow Template friend operator:

```
// Note the declaration of the template friend operator.
template<class T>
class A_list
    // constructor with size of the list
   A_list(int size);
   // destructor
   ~A_list();
   // copy constructor
   A_list(A_list<T>& b);
   // assignment operator
   A_list<T>& operator=(const A_list<T>& b);
    // friend insertion operator
   template <class TT>
    friend ostream& operator<<(ostream& outs, const A_list<TT>& rhs);
private:
   T *p;
   int size;
```

Iterators

⇒ An iterator is a generalisation of a pointer. It is an object that identifies an element of a sequence. Different containers have different iterators.

```
#include <vector>
vector<int> v = \{1, 2, 3, 4, 5\};
// mutable iterator
vector<int>::iterator e;
// bidirectional access
e = v.begin();
++e;
// print v[1]
cout << *e << endl;
// print v[0]
cout << *e << endl;
// random access
e = v.begin();
// print v[3]
cout << e[3] << endl;</pre>
// change an element
e[3] = 9;
```

 \Rightarrow Constant iterator

 \Rightarrow Reverse iterator

 \Rightarrow Example implementation of an iterator for a custom linked list class

```
#include <iostream>
#include <ostream>
#include <algorithm>
// node of the linked list
template <class T>
class LListNode
public:
    // constructor for a new node
    LListNode(T new_data = T(), LListNode<T>* new_next = nullptr) :
   data(new_data), next(new_next) {};
    // friends
   friend class LList<T>;
   template <class TT>
    friend ostream& operator<<(ostream& outs, const LList<TT>& rhs);
private:
   // data element
   T data{T()};
    // next pointer
   LListNode<T>* next{nullptr};
};
// linked list declaration
template <class T>
class LList
public:
    // default constructor
   LList() : head(nullptr) {};
    // copy constructor
   LList(const LList<T>& rhs) { *this = rhs; };
    // assignment operator
   LList<T>& operator=(const LList<T>& rhs);
    // virtual destructor
   virtual ~LList() { clear(); };
    // clear (free) the list
   void clear();
    // get head
   LListNode<T>* get_head() const { return head; };
    // get node
   LListNode<T>* get_node(int n=0) const;
    // insert a new data element at the head of the list
   void insert_at_head(T new_data);
   // insert a new data element at the end of the list
   void insert_at_end(T new_data);
   // insert a new element at a given pointed node
   void insert_at_point(LListNode<T>* ptr, T new_data);
    // remove the data element at the head of the list
    T remove_head();
    // test for empty list
   bool is_empty() const { return head == nullptr; };
    // count of the elements stored in the list
```

```
int size() const;
    // insertion operator
    template <class TT>
    friend ostream& operator<<(ostream& outs, const LList<TT>& rhs);
    // iterator type
    class iterator;
    // iterator to first element
    iterator begin() { return iterator(head); }
    // iterator to one beyond last element
    iterator end() { return iterator(nullptr); }
private:
    // head pointer
    LListNode<T>* head{nullptr};
    // recursive copy list function
    LListNode<T>* recursive_copy(LListNode<T>* rhs);
};
// iterator class for the linked list
template <class T>
class LList<T>::iterator
public:
   iterator(LListNode<T>* p) : curr{p} {}
    // prefix increment, returns a reference!
    iterator& operator++() { curr = curr->next; return *this; }
    T& operator*() const { return curr->data; }
    bool operator==(const iterator& b) const { return curr == b.curr; }
    bool operator!=(const iterator& b) const { return curr != b.curr; }
private:
    LListNode<T>* curr{nullptr};
// example usage
LList<int> data_list;
// inserts element into the list
data_list.insert_at_head(45);
data_list.insert_at_head(-21);
data_list.insert_at_end(127);
// prints data_list = (-21) -> (45) -> (127)
cout << "data_list_=_" << data_list << endl;</pre>
// prints data_list.size() = 3
cout << "data_list.size() == " << data_list.size() << "\n\n";</pre>
// applies standard algorithms on the custom linked list
LList<int>::iterator p = find(data_list.begin(),data_list.end(),45);
// checks if the element has been found
// standard algorithms return the end of a sequence,
// i.e. the end iterator, to indicate failure
if ( p != second_list.end() )
        cout << "found_element_" << *p << "\n\n";</pre>
```

```
cout << "cannot_find_element_" << 45 << "\n\n";

// write access
*p = 180;

// prints data_list = (-21) -> (180) -> (127)
cout << "data_list_=_" << data_list << endl;</pre>
```

Containers

 \Rightarrow Sequential containers: list

```
#include <list>
list<double> data = {1.32,-2.45,5.65,-8.93,2.76};
// adds elements
data.push_back(9.23);
data.push_front(-3.94);
// bidirectional iterator, no random access
list<double>::iterator e;
// advance
e = data.begin();
advance(e,2);
// erases element 5.65
data.erase(e);
// print out the content
for (e = data.begin(); e != data.end(); e++)
   cout << *e << endl;
// range-for-loop
for (auto x : data)
    cout << x << endl;
```

 \Rightarrow Adapter containers: stack

```
#include <stack>
stack<double> numbers;

// push on the stack
numbers.push(5.65);
numbers.push(-3.95);
numbers.push(6.95);

// size
```

```
cout << numbers.size()

// read top data element
double d = numbers.top();

// pop top element
numbers.pop();</pre>
```

 \Rightarrow Associative containers: set, ordered according to its keys

⇒ Associative containers: map, ordered according to its key in pairs (key,value)

```
#include <map>
#include <utility>
#include <string>
// initialisation
map<string,int> dict = { "one",1}, {"two",2} };
pair<string,int> three("three",3);
// insertion
dict.insert(three);
dict["four"] = 4;
dict["five"] = 5;
// make_pair
pair<string,int> six;
six = make_pair<string,int>("six",6);
dict.insert(six);
// iterator
map<string,int>::iterator two;
// find
```

```
two = dict.find("two");

// erase
dict.erase(two);

// range-for-loop
// inside the loop n is a pair
// the key is n.first and the value is n.second
for (auto n : dict)
    cout << "(" << n.first << "," << n.second << ")" << endl;</pre>
```

 \Rightarrow Associative containers: multimap, ordered according to its key in pairs (key,value), keys can be repeated

Algorithms

Provided by the C++ standard template library (STL).

 \Rightarrow find

```
#include <algorithm>
#include <vector>

vector<int> v = {6,2,7,13,4,3,1};
vector<int>::iterator p;

// find
// points to the first occurrence of 13 in v
p = find(v.begin(),v.end(),13);
```

 \Rightarrow find_if

```
bool test_greater_than_5(int x) { return x>5; }
// find_if
// general search, stops as soon as the predicate is satisfied
// points to the first occurrence of an element greater than 5 in v
p = find_if(v.begin(), v.end(), test_greater_than_5);
```

⇒ Function object

```
// function object
class Test_greater
{
public:
    Test_greater(int x) : n{x} {}
    bool operator() (const int x) const { return x>n; }
private:
    int n{0};
};

// find_if
// general search, stops as soon as the predicate is satisfied
// points to the first occurrence of an element greater than 7 in v
p = find_if(v.begin(), v.end(), Test_greater(7));
```

 \Rightarrow accumulate

```
#include <algorithm>
#include <vector>
#include <list>
#include <numeric>
#include <functional>

// accumulate
// adds the values from a sequence
// the last parameter is the initial value
// the return type is the type of the initial value!
long res = accumulate(v.begin(),v.end(),long(0));

// generic accumulate performing multiplication instead of sum
// passes a function object multiplies<int>() defined in <functional>
double res = accumulate(v.begin(),v.end(),1.0,multiplies<int>());
```

 \Rightarrow Inner product

```
// inner product
vector<int> v1 = {-2,2,4,11,-4,3,1};
vector<int> v2 = {4,2,4,18,5,3,1,7,9,};
long res = inner_product(v1.begin(), v1.end(), v2.begin(),long(0));
```

 \Rightarrow copy between different containers

```
list<double> data = {1.32,-2.45,5.65};
vector<int> int_data(5);

// copy data from the list of doubles to the vector of integers
copy(data.begin(),data.end(),int_data.begin());
```

⇒ copy between a container and an output stream. A container can be initialised by the elements retrieved via a pair of iterators.

 \Rightarrow Merge sort

```
// merge sort
sort(v.begin(), v.end());
```

 \Rightarrow Binary search

```
// binary search
bool found;
found = binary_search(v.begin(), v.end(), 3);
```

 \Rightarrow reverse

```
// reverse
reverse(v.begin(), v.end());
```
